#### Abstract

Abstrak Salah satu teknik data mining adalah Association Rule yang sering disebut dengan prosedur Market Basket Analysis untuk mencari pengetahuan tentang pola pembelian konsumen. Riset ini menggunakan algoritma Frequent Pattern Growth (FP-Growth). FP-Growth dalam membentuk itemset dilakukan dengan membuat struktur data FP-Tree. Data yang digunakan memanfaatkan transaksi Klinik selama dua tahun. Analisis dilakukan untuk mempertimbangkan keputusan bagi pemangku kepentingan informasi di Klinik. Hasilnya diperoleh 118 rule dengan nilai minimal 30\% support dan 75\% confidence. Aturan yang dihasilkan 100\% jika beli INJ Piralen maka beli INJ Ranitidine, $100 \%$ jika beli Genoint maka beli Genoint SK, jika beli Gastritis Cap maka beli 100\% Myalgia Cap, jika beli Sanbe SP NACL Liquid maka beli 100\% Glucose Dextrose Liquid, kalau beli Omecidal beli Omedeson 100\%, dan kalau beli Omeprazole beli Gludepatik 87\%. Riset ini membantu pemilik Klinik menentukan pola dan menampilkan obat yang paling laris dibeli konsumen.

Kata Kunci: Aturan Asosiasi, Algoritma FP-Growth, Data Mining

#### Abstract

One data mining technique is the Association Rule which is often referred to as Market Basket Analysis procedure to seek knowledge about customer purchasing patterns. This research used Frequent Pattern Growth (FP-Growth) algorithm. FP-Growth in forming itemset is done by creating an FP-Tree data structure. The data utilized the Clinic transaction for two years. The analysis was carried out to consider decisions for information stakeholders at the Clinic. The results obtained 118 rules with a minimum value of $30 \%$ support and $75 \%$ confidence. The resulting rules are 100\% if you buy INJ Piralen then buy INJ Ranitidine, 100\% if you buy Genoint then buy Genoint SK, if you buy Gastritis Cap then you buy 100\% Myalgia Cap, if you buy Sanbe SP NACL Liquid then you buy $100 \%$ Glucose Dextrose Liquid, if you buy Omecidal, you buy Omedeson 100\%, and if you buy Omeprazole, you buy Gludepatic 87\%. This research helped Clinic owners define the pattern and display the most in-demand drugs purchased to customer.

Keywords: Association Rules, Data Mining, FP-Growth Algorithm

## INTRODUCTION

Citra Sehat Clinic is a health care provider with a pharmacy and doctor's practice services. The Clinic located in the Tigaraksa area sells various kinds of medicines. This pharmacy can provide services for purchasing drugs, starting from a doctor's prescription or general medicine needed by the community. In
this case, the pharmacy has many transaction data that comes in every year, giving rise to drug purchasing patterns by finding the drug data set that appears most often in a transaction. Therefore, management must know which drugs most frequently purchased and arrange the layout to speed up the transaction process. For example, when a customer buys cough medicine, it will coincide
with headache medicine. If the pattern of drug purchases is unknown, it will be hard to determine the layout of the drug, the most frequently purchased drug, and the promotions. Therefore, an analysis of association rules will conduct to define drug patterns purchased.

Data mining is a way of extracting information from a large data set (database). There are many techniques in the data mining process, one of them is the Association Rules. Association Rules are rules for finding highfrequency patterns between sets of items by determining support and confidence. The purpose of data mining is to find association rules from a large database.

Association Rule is one method that aims to find patterns that often appear among many transactions, each transaction consisting of several items [1]. Association Rule is also used in analyzing the Apriori algorithm. A few researchers focused on doing the Association Rule method. Association rules are widely used for the process of analysis and selection. Association Rules have been used in analyzing clay purchase selection [2]. Some are used in the fields of education, sales, transportation, health, and others [3] - [9]. These researches are aimed at seeing interesting knowledge from a large database.

The FP-Growth algorithm which is one of an Association Rules technique will be used. The FP-Growth algorithm is used with a minimum of $30 \%$ support and $75 \%$ confidence. The purpose of the research is to test the FP-Growth with the Weka application
so that the best association rules are obtained. The FP-Growth algorithm, which is the Association Rules technique, can determine the best pattern to use as a reference in obtaining buying patterns. FP-Growth is an algorithm with a strong data structure, resulting in the best opportunity to generate rules. The data used is the transaction from the Clinic at Tigaraksa, Tangerang Banten for two years. This research intends to give the best recommendations for the Clinic.

## A. Knowledge Discovery in Database (KDD) Stage

Data mining is one of a series of processes of finding knowledge in a database [10]. Data mining is not a completely new field. One of the difficulties in defining data mining is the fact that data mining inherits many aspects and techniques from established fields of science. The terms data mining and Knowledge Discovery in Database (KDD) are often used interchangeably to describe the process of extracting hidden information in a large database. The KDD process as shown in Figure 1.

Understanding the problems to be faced and having the context to propose viable and tangible solutions is needed. The study of nature, limits, and rules of the data or information and determining the goals to be achieved are necessary. Available data is selected to learn from data sets with predetermined goals. Then integrate them into one data that can help analyze and achieve the
target. This information can be found on the same resource or also distributed. In the preprocessing stage, the reliability of the information, namely the implementation of tasks that guarantee the usability of the data, was determined. For this reason, data cleaning, the treatment of missing data, or removing outliers proceeded. It implies omitting variables or attributes with missing data or omitting useless information like text, images, and more. At the data transformation, data quality is transforming into the number reduction of variables in the data set or changing numeric values to categorical ones. In data mining phase, an appropriate data mining process can select whether classification, regression, or clustering, according to the goals set. Furthermore, the two techniques or algorithms are selected to look for patterns and gain knowledge. Metalearning focuses on explaining why an algorithm works better for a particular problem. There are various possible ways of picking it for each technique. Each algorithm
has its essence and its way of working and getting results. Knowing what candidate properties to use and seeing which best fits the data is advisable. Finally, once the technique is selected, the next step is to apply it to the data that has been selected, cleaned, and processed. The execution of the algorithm in some trying parameters may optimize the result. These parameters vary according to the method chosen. Once the algorithms were applied to the data set, the generated patterns were evaluated and the obtained performance was verified. It will meet the goals set in the first phases. There is an evaluation technique called Cross-Validation. It performs data partition, dividing it into training and test data. If all the steps are followed correctly and the evaluation results are satisfied, the last stage is simply applying the knowledge found to the context and beginning to solve its problems. On the contrary, it is necessary to return to the previous stages to make some adjustments, analyzing from the data selection to the evaluation stage.

Figure 1. Knowledge Discovery in Database (KDD)

## B. Data Mining

Data Mining is the discovery of new information by looking for certain patterns or rules from a large database [1]. Data mining is one of a task series that can be performed, namely [11] :

1. Description

The process of finding data to describe patterns and trends contained in the data.
2. Estimate

Estimates are almost the same as classifications, except that the target variable is more numerical rather than categorical. The model is built using a complete record that provides the value of the target variable as a prediction.
3. Prediction

Prediction is almost the same as classification and estimation, except that in predication the value of the results will be in the future.
4. Classification

In classification, there are target variable categories.
5. Clustering

Clustering is a grouping of records, observations, or pay attention and form classes of objects that have similarities.
6. Association

The task of association in data mining is to find attributes that appear at one time. This stage looks for combinations of items that meet the minimum requirements of value.

## C. Association Rule

The association rule will use training data as the notion of data mining, to produce knowledge. Knowledge to find out shopping items that are often bought simultaneously at one time. Association rules in the form of "if ... then ..." is knowledge generated from the association rules function [12].

This stage looked for a combination of items that meet the minimum requirements of the support value in the database. The value of an item's support is obtained by the following formula [2]:

$$
\begin{equation*}
\text { Support (A) }=(\mathrm{JT}(\mathrm{~A})) / \mathrm{T} \times 100 \% \tag{1}
\end{equation*}
$$

Based on Equation (1), then A is the name of the item, JT (A) the appearance of item A on the transaction, and T is the total transaction. In general, the association rule is a two-step process [13]:

1. Find all frequent itemset, with the understanding that each itemset will often appear with a specified minimum support (min-sup) value.
2. Generate strong association rules from frequent itemset. Understanding these rules must meet minimum support and minimum confidence.

After all, high-frequency patterns have been found, then the association rules that are eligible for confidence are searched by calculating the confidence rules of the association $\mathrm{A} \rightarrow \mathrm{B}$. The confidence value of the $\mathrm{A} \rightarrow \mathrm{B}$ rule is obtained from the following formula [2] :

$$
\begin{equation*}
\text { Confidence } \mathrm{P}(\mathrm{~A} \mid \mathrm{B})=\Sigma \frac{\mathrm{Transactions} \mathrm{Containing} \mathrm{~A} \mathrm{and} \mathrm{~B}}{\text { Transactions Containing } \mathrm{A}} \times 100 \% \tag{2}
\end{equation*}
$$

Based on Equation (2), $\mathrm{P}(\mathrm{A} \mid \mathrm{B})$ is an item name, the transaction containing A and $B$ is the appearance of items $A$ and $B$ on the transactions, and the transactions containing A is the appearance of item A on the transaction.

## D. FP-Growth Algorithm

FP-Growth is one of the algorithms included in the Rule Mining Association. FPGrowth is an algorithm that has a strong data structure to produce a good rule generating opportunity. FP-Growth is used to determine the best pattern that will be used as a reference in getting purchasing items at the Clinic. Unlike in the Apriori algorithm, there is no need for candidate generation with FP trees, and the frequently occurring item sets are discovered by simply crossing the FP tree [4]. Any set of records valid rules and patterns can be created with this FP tree. FP growth was implemented for book recommendations from a library database. The accuracy given is $60.78 \%$ [14].

The FP-Growth algorithm is divided into three main steps [15] :

1. The generation phase of a Conditional Pattern Base, a sub-database that contains a prefix path and a suffix pattern. The generation of a conditional pattern base is obtained through FPtrees that have been built before.
2. Conditional FP-tree generation stage. At this stage the support count of each item in each conditional pattern base is added up, then each item that has support count greater than the minimum support count will be raised with a conditional FP-tree.
3. The frequent itemset search stage if the Conditional FP-tree is a single path, then a frequent itemset is obtained by combining items for each FP-tree conditional.

## RESEARCH METHOD

The research method is the sequence of frameworks that must be followed, the order of the flow of this research is a description of the steps that must be passed so that this research can run well. The research method process is as shown in Figure 2.

Figure 2. Research Flow

Based on Figure 2, the sequence of research flow is explained as follows :

1. Data Collection used to collect data and information needed in analysis activities. The data collection used was transaction data of a Clinic for two years, 2017-2018.
2. Analyzing Data uses the FP-Growth algorithm. Data processing in the algorithm is as material for analyzing transaction data.
3. Implementation with Weka, a test for all data that will be tested with the Weka application using the FP-Growth algorithm.
4. Results Analysis, the results obtained by the FP-Growth algorithm. At this stage, an analysis of the results obtained from the association rules is formed.

## RESULT AND DISCUSSION

## A. Data Collection

The data used is transaction data at a Clinic in Tangerang, Banten for two years. Data representation is done by forming
transaction patterns every day. If there is the same drug name found then it will be included in the next transaction. There are as many as 81 different kinds of drugs, 700 transactions, with 9407 data on all sales. The drug attributes analyzed in the test were 16 different types of drugs, included in one itemset in manual calculations. Testing will be carried out only on a data sample of 36 transactions with all data of 700 transactions. The data transaction attributes will be the date, number of transactions, the name and the code of the drugs.

## B. Analyzing Data

The sample of data to be tested in this study were 81 drugs. There are 36 drug sales transaction data at the Clinic. The name of the drug is initials made to reduce the amount of drug writing so that the drug data is not exchanged. The example drug initials shown are 16 items. Drug initials can be seen in Table 1.

These initial drug names will be used as a sample of 36 transaction data collection. Sample transaction data can be seen in Table 2.

Table 1. Transaction Data

| 36 | N | N | N | N | N | N | N | $\ldots$ | Y |

The next step is to form a binary symmetric tabulation to see the appearance of the drug in the transaction. Sample transaction data can be seen in Table 3.

## C. FP-Growth Algorithm

The data analysis phase will be carried out using the FP-Growth method. Two inputs are needed to find the rules of the association, determining the minimum support (emergence value) and minimum confidence (trust value). After that, an itemset filter is performed to form an FP-tree, then the association rule process is carried out. Association rule formed must meet the minimum value specified by the user [12]. The author takes a minimum support
value of $30 \%$ and minimum confidence of $75 \%$ from the interview.

These values are the limit of the support and confidence value for the data mining calculation process. This stage looked for 1 itemset that meets the $30 \%$ support using the equation (1). After searching for 1 itemset as many as 16 items were obtained, the items are sorted from the highest frequency. Table 4 below is the result of forming 1 itemset.

The obtained items with above $30 \%$ support are A, D, E, G, J, T, W, Z, $\mathrm{L}_{2}, \mathrm{O}_{2}, \mathrm{U}_{2}$, $Y_{2}, A_{3}, G_{3}, Q_{3}$, and $Z_{3}$. These 16 items will be included in the FP-Tree development transaction. Table 5 follows the highest frequency adjusted transactions.

Table 4. The occurrence of High Frequency Based Items

| Initial | Count | Support (\%) |
| :---: | :---: | :---: |
| Z | 23 | 63,89 |
| J | 22 | 61,11 |

The establishment of FP-Tree is a compressed data storage structure. FP-Tree is built by mapping each transaction data to each path. FP-Tree is formed by a root that is labeled null. Each node of FP-Tree contains three important information, which is the item label that informs the type of item being presented, the support count represents the number of paths through that node, and the connecting pointers that connect the nodes with the same item label between paths are marked with arrow lines. Thicker knots show the reading of each transaction. The steps to build FP-Tree are as follows :

## 1. TID Readings 1

In TID 1 there are items $\left\{G_{3}, U_{2}, A_{3}\right.$,
$\left.\mathrm{O}_{2}, \mathrm{~A}\right\}$ which then form all path $\mathrm{G}_{3}-$ $>\mathrm{U}_{2}->\mathrm{A}_{3}->\mathrm{O}_{2}->$ A. See Figure 3 for more details.
2. TID Readings 2

After reading TID 1 , the next reading TID 2 is $\left\{Z, J, Y_{2}, G_{3}, E, L_{2}, T, U_{2}, A_{3}\right.$, $\left.\mathrm{O}_{2}, \mathrm{D}, \mathrm{Q}_{3}, \mathrm{Z}_{3}\right\}$. In TID 2 you must make a new track again because Z item has never been missed. For more details can be seen in Figure 4.
3. TID Readings 36

After reading all the TID 1 to TID 2 transactions, the tree form is obtained at the last transaction, which is the 36 FP-Tree TID form. Figure 5 follows is the FP-Tree of all transactions.

Figure 3. FP-Tree TID 1

Figure 4. FP-Tree TID 2

Figure 5. FP-Tree TID 36

In finding frequent itemset, it is necessary to open 36 trees that have been made which are called subtree or tree (trees whose roots are descended from the root of the parent tree). The subtree search starts from the item that has the smallest support $\left(Z_{3}\right)$ to the largest $(Z)$. The process of forming a subtree explains in the following:

- $\quad Z_{3}$ Item Track

All tracks that have $Z_{3}$ items are displayed, tracks that do not have $\mathrm{Z}_{3}$ items are deleted. The reference path taken is the complete FP-Tree on TID 36. The path of $Z_{3}$ item can be seen in Figure 6.

- Z Item Track

The opening process of the FP-Tree tree on Z 3 to Z items is the lowest to highest frequency items. Then next to the item with the highest frequency is Z item. All tracks that have Z item is displayed; tracks that do not have Z item are deleted. The reference path taken is the complete FP-Tree on TID 36. The path of Z item can be seen in Figure 7.

Z path has a single node, Z, which has the highest count value. From the FP-Tree generation that has been carried out, the results of Conditional Pattern Base and Conditional FP-Tree can be seen in Table 6.

Figure 6. Tracks That Have $Z_{3}$ Item

Figure 7. Tracks That Have Z Item
Table 6. Conditional Pattern Base and Conditional FP-Tree

| Suffix | Conditional Pattern Base | Conditional FP-Tree |

Table 6 contains a suffix, conditional pattern base, and conditional FP-Tree. A suffix is the name of the item that is included in the frequent list and is sorted by the smallest to largest support values. Conditional pattern base is the reading of FP-Tree nodes after the formation of TID 36 and is seen according to the suffix of the item, starting from the item with the smallest support value, Z3 item, all paths ending in Z3 are displayed, paths that do not have Z 3 item deleted. Z has no path because Z is a single path that has no other vertices, and Z is the item with the largest support value. Conditional FP-Tree is the number of items that appear on the conditional pattern base (on each path of an item) and what items are seen in the reading at each node item.

From the results of the conditional pattern base and conditional FP-Tree, we will get a combination of itemset, the largest item appearing on the FP-Tree
conditional then combined with suffix (according to the path of the item). The confidence calculation uses equation (2). Table 7 is a combination of items that meet the value of support and confidence.
Association rules are obtained by fulfilling minimum support of $30 \%$ and $75 \%$ confidence. Example of reading the association rules, $\mathrm{D}=>\mathrm{E}$ can be read "if you buy D (Omecidal) then you will buy E (Omedeson) with support $38,89 \%$ and $80,85 \%$ confidence", and $L_{2}=>Y_{2}$ can be read "if you buy $L_{2}$ (NACL liquid Sanbe SP) will then buy $\mathrm{Y}_{2}$ (Glucose Dextrose Liquid) with $100 \%$ confidence".

## 4. Implementation

Implementation is carried out using the Weka application, with minimum support of $30 \%$ and confidence of $75 \%$. The test results obtained 118 rules and it can be seen in Figure 8.

Table 7. Confidence Calculation Results and Association Rules Results

| Itemset | Support | Support $(\%)$ | Confidence Eq. | Confidence $(\%)$ |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}=>\mathrm{E}$ | 14 | 38,89 | $\{\mathrm{D}, \mathrm{E}\} / \mathrm{D}$ | $14 / 14=100$ |
| $\mathrm{E}=>\mathrm{D}$ | 14 | 38,89 | $\{\mathrm{E}, \mathrm{D}\} / \mathrm{E}$ | $14 / 17=80,85$ |
| $\mathrm{O}_{2} \Rightarrow>\mathrm{U}_{2}$ | 13 | 36,11 | $\left\{\mathrm{O}_{2}, \mathrm{U}_{2}\right\} / \mathrm{O}_{2}$ | $13 / 15=87,80$ |
| $\mathrm{U}_{2}=>\mathrm{O}_{2}$ | 13 | 36,11 | $\left\{\mathrm{U}_{2}, \mathrm{O}_{2}\right\} / \mathrm{U}_{2}$ | $13 / 16=81,81$ |
| $\mathrm{G} \Rightarrow>\mathrm{W}$ | 13 | 36,11 | $\{\mathrm{G}, \mathrm{W}\} / \mathrm{G}$ | $13 / 15=87,80$ |
| $\mathrm{~W} \Rightarrow>\mathrm{G}$ | 13 | 36,11 | $\{\mathrm{~W}, \mathrm{G}\} / \mathrm{W}$ | $13 / 17=81,81$ |
| $\mathrm{~A}_{3}=>\mathrm{G}_{3}$ | 16 | 44,44 | $\left\{\mathrm{~A}_{3}, \mathrm{G}_{3}\right\} / \mathrm{A}_{3}$ | $16 / 16=100$ |
| $\mathrm{G}_{3}=>\mathrm{A}_{3}$ | 16 | 44,44 | $\left\{\mathrm{G}_{3}, \mathrm{~A}_{3}\right\} / \mathrm{G}_{3}$ | $16 / 18=93,61$ |
| $\mathrm{~L}_{2}=>\mathrm{Y}_{2}$ | 17 | 47,22 | $\left\{\mathrm{~L}_{2}, \mathrm{Y}_{2}\right\} / \mathrm{L}_{2}$ | $17 / 17=100$ |
| $\mathrm{Y}_{2}=>\mathrm{L}_{2}$ | 17 | 47,22 | $\left\{\mathrm{Y}_{2}, \mathrm{~L}_{2}\right\} / \mathrm{Y}_{2}$ | $17 / 18=94$ |
| $\mathrm{~J}=>\mathrm{Z}^{2}$ | 20 | 55,56 | $\{\mathrm{~J}, \mathrm{Z}\} / \mathrm{J}$ | $20 / 22=90,16$ |
| $\mathrm{Z}=>\mathrm{J}$ | 20 | 55,56 | $\{\mathrm{Z}, \mathrm{J}\} / \mathrm{Z}$ | $20 / 23=87,30$ |

Figure 8. Results of the FP-Growth Association Rules
The generated rules from the test are from all existing data. From the association 118. The figure showed only 25 rules, with different levels of confidence. $\mathrm{G}_{3}$ => $A_{3}$ rule can be read as "if you buy $\mathrm{G}_{3}$ (INJ Piralen) then you will buy $\mathrm{A}_{3}$ (INJ Ranitidine) with $100 \%$ confidence", and $\mathrm{L}_{2} \Rightarrow \mathrm{Y}_{2}$ can be read as "if you buy $\mathrm{L}_{2}$ (Sanbe NACL Liquid) then you will buy $\mathrm{Y}_{2}$ (Glucose Dextrose Liquid) with $100 \%$ confidence".

## D. Results Analysis

Data samples are 36 transactions taken rules results, obtained patterns of purchasing drugs are \{INJ Piralen, INJ Ranitidine\}, \{Genoint SK, Genoint\}, \{Gastritis Cap, Myalgia Cap\}, \{NACL Sanbe SP Liquid, Dextrose Glucose Liquid\}, \{Omecidal, Omedeson\}, \{Omeprazole, Gludepatic\}, \{Abbocath 24, Ointment 24\}, and \{Mikrogynon, Gludepatic\}. The association rules obtained are the result of the analysis of drug purchase patterns at the Clinic and in Tabel 8.

Table 8. Analysis of Results

| If | Then | Confidence (\%) |
| :---: | :---: | :---: |
| INJ Piralen | INJ Ranitidine | 100 |
| Genoint SK | Genoint | 100 |
| Gastritis Cap | Myalgia Cap | 100 |
| NACL Sanbe SP Liquid | Dextrose Glucose Liquid | 100 |
| Omeprazole | Gludepatic | 80 |
| Omecidal Tab | Omedeson Tab | 100 |

## CONCLUSION AND SUGGESTION

Information was successfully obtained from the results of data mining analysis in the form of drug purchase patterns at the Clinic in Tangerang, Banten with 2 years data collection. The pattern of drug purchases at the Clinic has the highest value of confidence in transactions. The results obtained with a minimum value of $30 \%$ support and $75 \%$ confidence are 118 rules.

The information obtained can be used by the owner of the Clinic in making decisions in determining the pattern of purchasing the most in-demand drugs. This information can be used to consider the layout decisions of goods, items that are always purchased, and to carry out promotions such as price discounts to customer.

This research is limited to analysis and has not been made in an application. The limitation of the Weka application that could not process large data is another obstacle in completing all existing transaction data. It can also compare with other algorithms such as Apriori and Filtered Associator. It expects to use sales transactions and more attributes to produce more accurate information for further research.
